## Problem set 1

---

### 1. Problems based on lecture

#### 1.1. Trends etc.

Figure 1: Fed Funds Rate and Inflation - Trends and Cycles

The first row in figure 1 shows monthly data for the Federal Funds Rate and CPI inflation for the period 1990m1-2018m8. The remaining rows show the Hodrick-Prescott trend and cycle (with smoothing parameter  $\lambda = 14400$ , the standard value for monthly data). Comment on the trends identified in the data and what they imply for the detrended data in the third row of the figure.

#### 1.2. Structural VARs (SVARs)

We are interested in the effects of interest rate (monetary policy) shocks on inflation. To begin, we estimate an unrestricted bivariate VAR with 4 lags in  $R_t$  (HP detrended) and  $\pi_t$  (demeaned but not detrended).

$$\begin{pmatrix} R_t \\ \pi_t \end{pmatrix} = \begin{pmatrix} 1.32 & -0.02 \\ 0.31 & 0.45 \end{pmatrix} \begin{pmatrix} R_{t-1} \\ \pi_{t-1} \end{pmatrix} \\
+ \begin{pmatrix} -0.25 & 0.03 \\ -0.23 & -0.18 \end{pmatrix} \begin{pmatrix} R_{t-2} \\ \pi_{t-2} \end{pmatrix} \\
+ \begin{pmatrix} -0.02 & -0.02 \\ -0.29 & 0.02 \end{pmatrix} \begin{pmatrix} R_{t-3} \\ \pi_{t-3} \end{pmatrix} \\
+ \begin{pmatrix} -0.10 & -0.07 \\ 0.26 & 0.03 \end{pmatrix} \begin{pmatrix} R_{t-4} \\ \pi_{t-4} \end{pmatrix} \\
+ \begin{pmatrix} u_{1t} \\ u_{2t} \end{pmatrix}$$

with

$$\begin{pmatrix} u_{1t} \\ u_{2t} \end{pmatrix} \sim N \left[ \begin{pmatrix} 0 \\ 0 \end{pmatrix}; \begin{pmatrix} 0.0147 & 0.0057 \\ 0.0057 & 0.0511 \end{pmatrix} \right]$$

Assume that interest rates react to shocks to inflation with a lag (this could be justified if the central bank does not have access to the current inflation data when it decides on policy, the Bernanke-Blinder (1992) identification), in which case the residuals of the bivariate VAR are related to the ‘structural’ disturbances by

$$\begin{pmatrix} u_{1t} \\ u_{2t} \end{pmatrix} = \begin{pmatrix} \theta_1 & 0 \\ \theta_3 & \theta_4 \end{pmatrix} \begin{pmatrix} e_{1t} \\ e_{2t} \end{pmatrix}$$

Calculate the coefficients  $\theta_1, \theta_3, \theta_4$  implied by the estimation. Note that we assume that the structural shocks are uncorrelated with each other and ‘standard normal’ (mean 0 and unity variance):

$$\begin{pmatrix} e_{1t} \\ e_{2t} \end{pmatrix} \sim N \left[ \begin{pmatrix} 0 \\ 0 \end{pmatrix}; \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right]$$

Note also that if a vector  $x$  has covariance matrix  $\Sigma$  then the vector  $Kx$  where  $K$  is a matrix, will have covariance matrix,  $K\Sigma K'$ .

### 1.3. Responses to shocks

The Excel spreadsheet MFE\_week3\_class.xlsx (available from the course webpage) is already part-programmed to help you produce impulse response functions from the estimate parameters of the VAR and different identification schemes.

Use the spreadsheet to calculate the impulse response functions to interest rate shocks and inflation shocks, under the assumption that shocks to inflation do not affect the interest rate within the period. To do this you simply need to transfer the values of  $\theta_1, \theta_3, \theta_4$  you just calculated into cells C3, C4, D3 and D4 of the spreadsheet (hint, D3 will be zero when inflation shocks do not contemporaneously affect interest rates). The spreadsheet checks whether your values of  $\theta_1, \theta_3, \theta_4$  are consistent with the variance-covariance matrix of residuals of the VAR in cells A13 and A14 (i.e.

have you done your calculation correctly). If they are then you should see some sensible impulse responses. What is the response of the economy to an interest rate shock? And to an inflation shock? Do these make intuitive sense? If not, what might be wrong?

## 2. Math Problems

### 2.1. Linearizations and log-linearizations - basic examples

In the appendix of the lecture 1 slides there is a discussion of linearizations and log-linearizations that you should read before attempting questions in this section. I assume that you are comfortable with simple calculus (basic differentiation) and the use of logarithms (logs) and exponential functions, though there is a refresher of some of their most relevant properties in the note on the webpage.

- Linearize  $5 + 3x^2$  around  $\bar{x}$ . Now linearize it around  $x = 1$  and  $x = 2$  (i.e. set  $\bar{x} = 1$  and  $\bar{x} = 2$ ). Roughly sketch a picture of the exact function and the approximating functions in the vicinity of the two specified approximation points. What is the value of the exact function and approximated functions at  $x = 1$ ,  $x = 2$  and  $x = 3$ ? Comment on the approximation errors.
- Log linearize  $15 - 3xy^2$  around  $(\bar{x}, \bar{y})$ . Now log-linearize it around  $(x, y) = (2, 3)$ . What is the value of the exact function at  $(1, 4)$  and what is the value of the approximating function.

### 2.2. Linearizations and log-linearizations - economics/financial example

Campbell and Shiller (1988) propose a very useful approximation to the return on an asset that enables the price of that asset to be expressed in terms of its future stream of returns and dividends. For a more extensive analysis (on which this is based) see the notes on Simon Gilchrist's website.

The realized return on an asset from  $t$  to  $t + 1$  is given by

$$R_{t+1} \equiv \frac{P_{t+1} + D_{t+1}}{P_t}$$

where  $P_t$  is *ex dividend* price of the asset in  $t$  and,  $D_t$  is the dividend paid in  $t$ . The return is made up of any dividend payment next period, plus the value of holding the asset next period, relative to the price paid today (i.e. capital gains). If we take logs of both sides we can express log returns as follows (you should understand these steps)

$$\begin{aligned} \log(R_{t+1}) &\equiv \log(P_{t+1} + D_{t+1}) - \log(P_t) \\ &\equiv \log\left(P_{t+1}\left(1 + \frac{D_{t+1}}{P_{t+1}}\right)\right) - \log(P_t) \\ &\equiv p_{t+1} - p_t + \log(1 + \exp(d_{t+1} - p_{t+1})) \end{aligned} \tag{1}$$

Note that at this point we have not yet taken any approximations but, as I mention in the notes, it has been setup in a way that is amenable to doing a linearization in the (lower case  $p_t \equiv \log(P_t)$  etc.) log forms of the variables, which is equivalent to a log-linearization in terms of the original versions of the variables.

- Linearize  $\log(1 + \exp(d_{t+1} - p_{t+1}))$  around  $(\bar{p}, \bar{d})$  and show that<sup>1</sup>

$$\log(1 + \exp(d_{t+1} - p_{t+1})) \approx k + (1 - \rho)(d_{t+1} - p_{t+1})$$

where

$$\begin{aligned}\rho &\equiv (1 + \exp(\bar{d} - \bar{p}))^{-1} \\ k &\equiv -\log(\rho) - (1 - \rho)\log(\rho^{-1} - 1)\end{aligned}$$

- Use the above approximation, along with equation (1), to obtain

$$p_t = \rho p_{t+1} + k + (1 - \rho)d_{t+1} - r_{t+1}$$

and, therefore,

$$p_t - d_t = \rho(p_{t+1} - d_{t+1}) + k + \Delta d_{t+1} - r_{t+1}$$

- Denoting  $\delta_t \equiv p_t - d_t$ , show that this implies (hint: keep substituting for  $\delta_{t+1}$ ,  $\delta_{t+2}, \dots$  on the RHS)

$$\delta_t = \frac{k}{1 - \rho} + \sum_{j=0}^{\infty} \rho^j (\Delta d_{t+1+j} - r_{t+1+j}) \quad (2)$$

Though you don't need to know this for the course, what is useful about this relation is that (with error only arising from the linear approximation) it shows that variation in the price dividend ratio must be accompanied by variations in future dividend growth, or future returns, or both. This holds *ex post* (subject only to approximation error from the linearization) but, in addition, the relationship holds *ex ante*. That is, one can take expectations of each side to say (note that  $E_t[p_t - d_t] = p_t - d_t$  as the price-dividend ratio in  $t$  is known at  $t$ ):

$$\delta_t = \frac{k}{1 - \rho} + \sum_{j=0}^{\infty} \rho^j E_t[\Delta d_{t+1+j} - r_{t+1+j}]$$

---

<sup>1</sup>Really you just need to show  $\log(1 + \exp(d_{t+1} - p_{t+1})) \approx \log(1 + e^{d-p}) + \frac{e^{d-p}}{1+e^{d-p}}(d_{t+1} - d) - \frac{e^{d-p}}{1+e^{d-p}}(p_{t+1} - p)$  and then try and rearrange terms appropriately. In fact, we should really be doing this linearization in terms of the (log) dividend-price ratio,  $dp_{t+1} \equiv d_t - p_{t+1}$  as there may be no natural constant steady state value of dividends or prices, due to growth (and/or inflation, if these are expressed in nominal terms) but let us ignore that for now.
